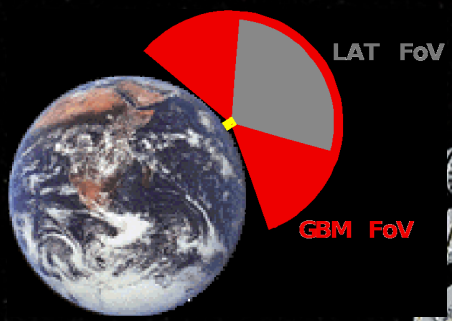
Fermi Symposium 2015

The *Fermi* Space Telescope

Gamma-ray Burst Monitor (GBM)

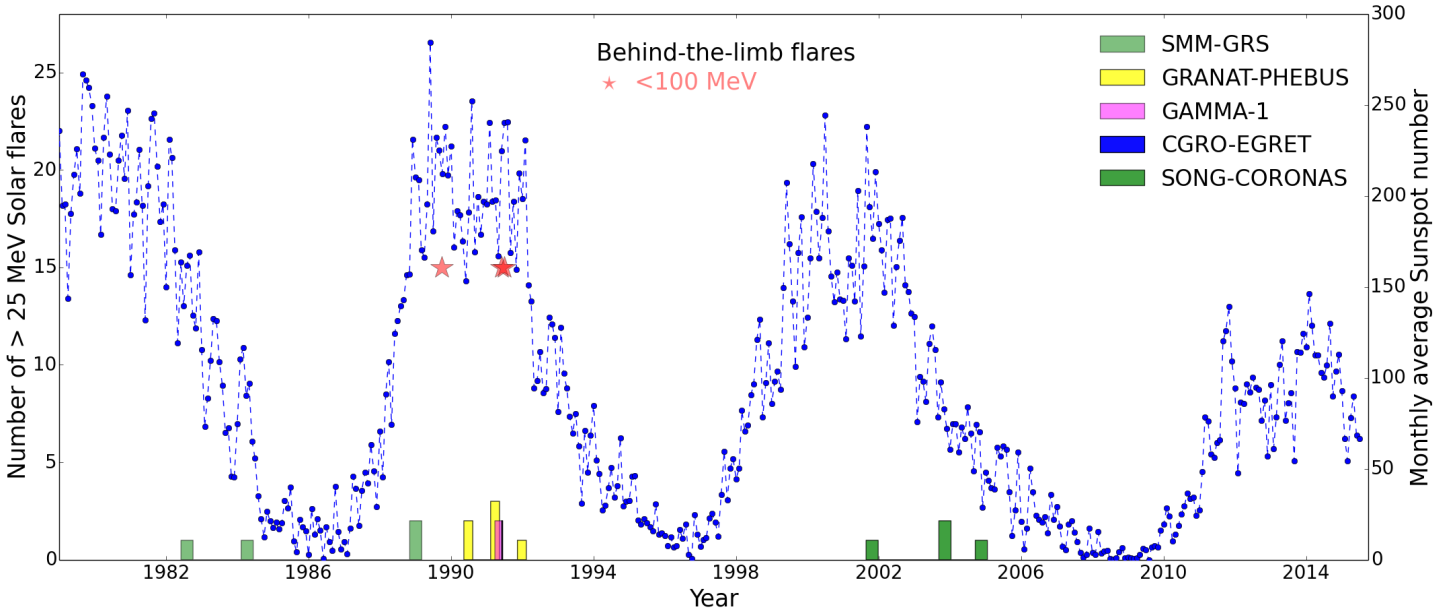
- 12 NaI and 2 BGO detectors
- Energy range: 8 keV–40 MeV
- Observes entire unocculted sky



The Large Area Telescope (LAT)

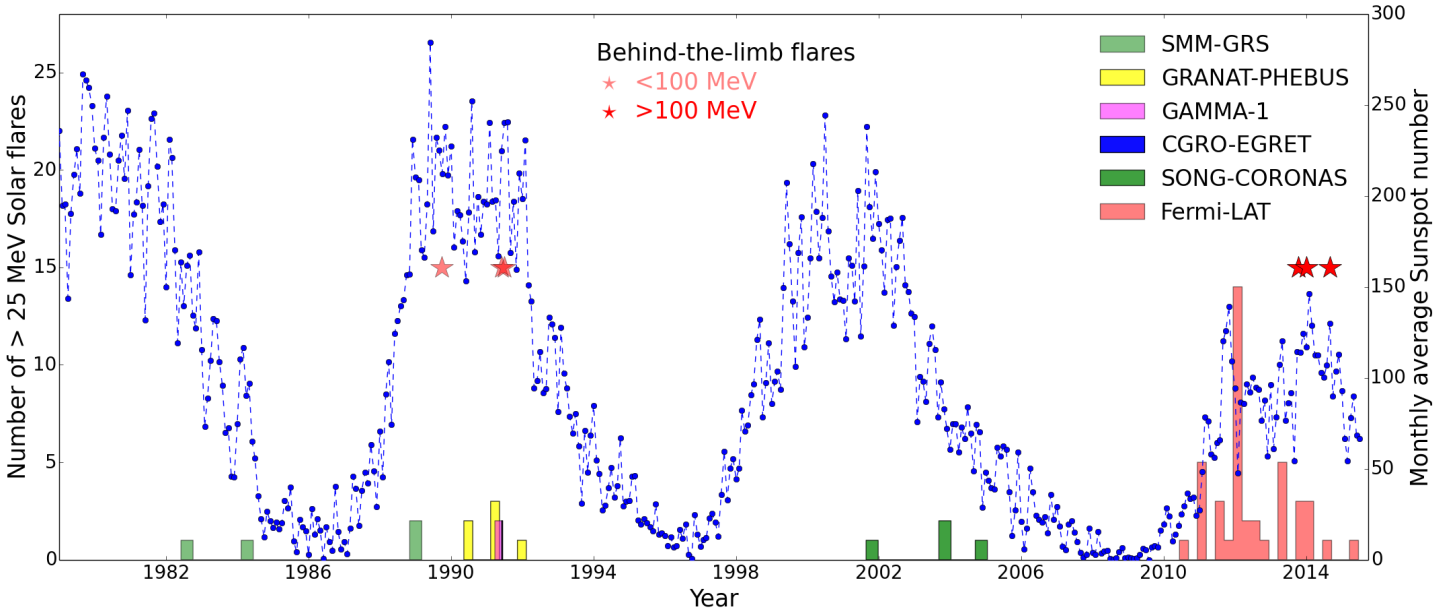
- Pair conversion telescope
- Energy range: 20 MeV–> 300 GeV
- Large field of view ($\approx$ 2.4 sr): 20% of the sky at any time, all parts of the sky for 30 minutes every 3 hours
- Observes the Sun for $\sim$20 – 40 min every 3 hours

Why study Solar flares with *Fermi*?



- Over the past 30 years limited sampling of solar flares with E>25 MeV
  - All of which were classified as GOES X class flares
  - Extended >100 MeV emission for ∼8 hours detected by EGRET
  - 3 behind-the-limb flares with E<100 MeV

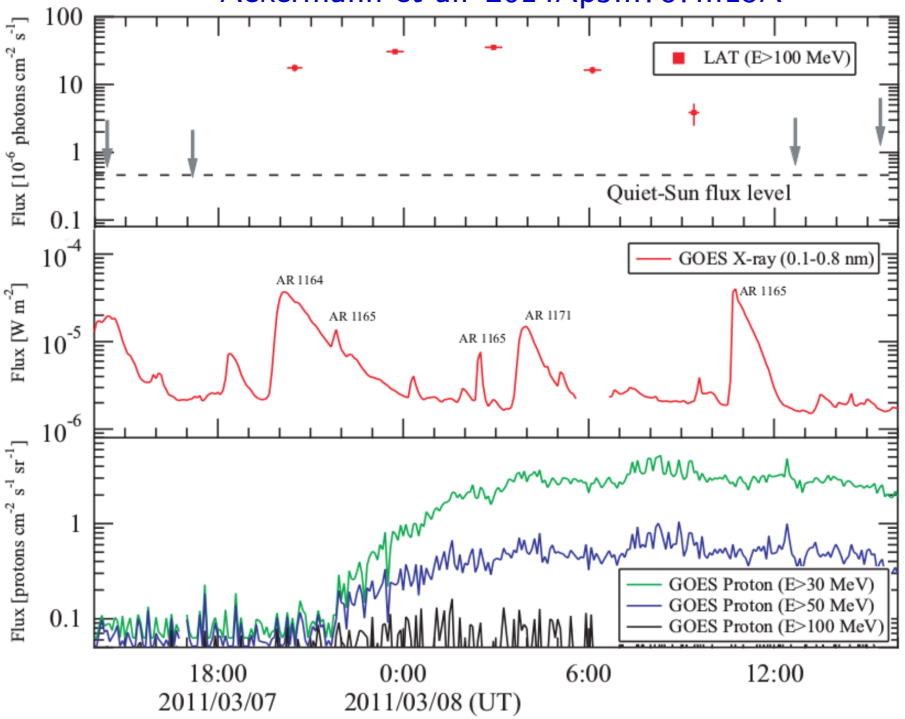
Why study Solar flares with *Fermi*?



- Over the past 30 years limited sampling of solar flares with E>25 MeV
  - All of which were classified as GOES X class flares
  - Extended >100 MeV emission for ∼8 hours detected by EGRET
  - 3 behind-the-limb flares with E<100 MeV
- *Fermi* has detected more than 40 Solar flares in first 7 years of mission
  - More than half are GOES M class
  - Extended >100 MeV emission for more than 20 hours
  - Including 3 behind-the-limb flares with >100 MeV emission

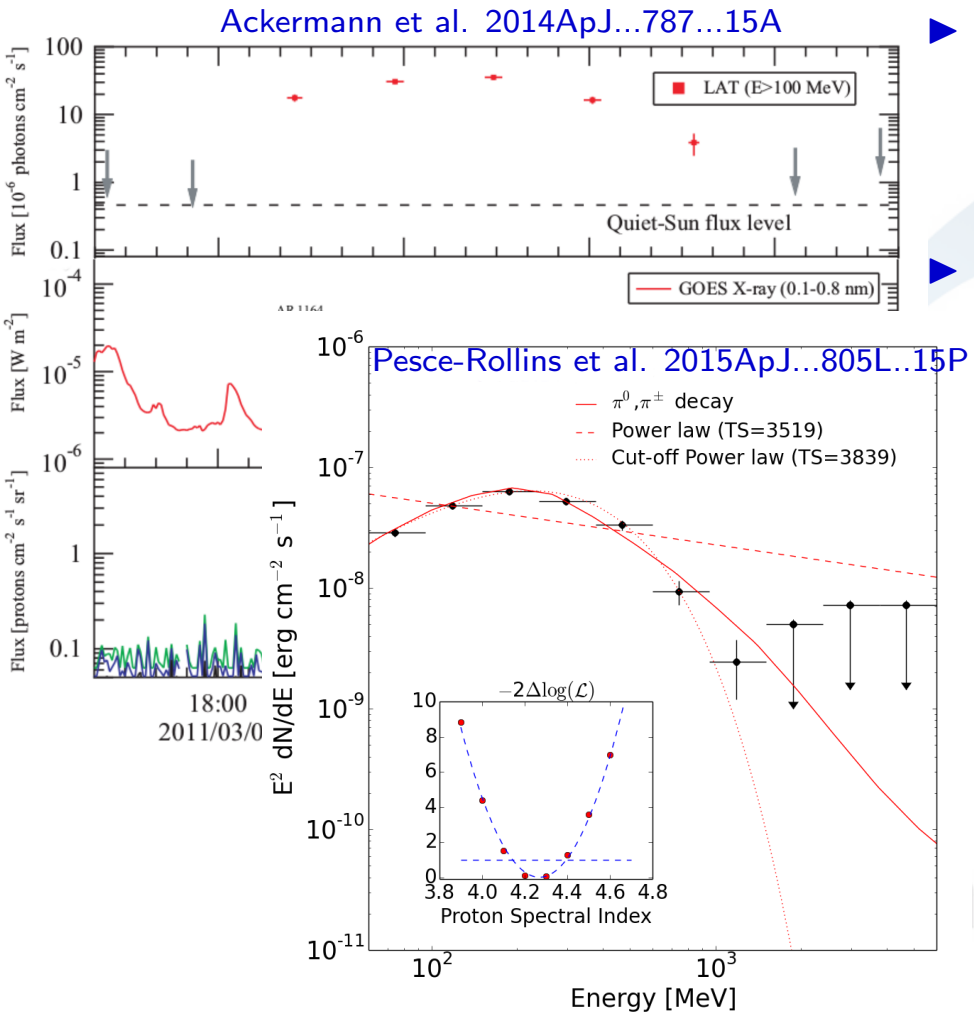
What have we learned so far?

Ackermann et al. 2014ApJ...787...15A



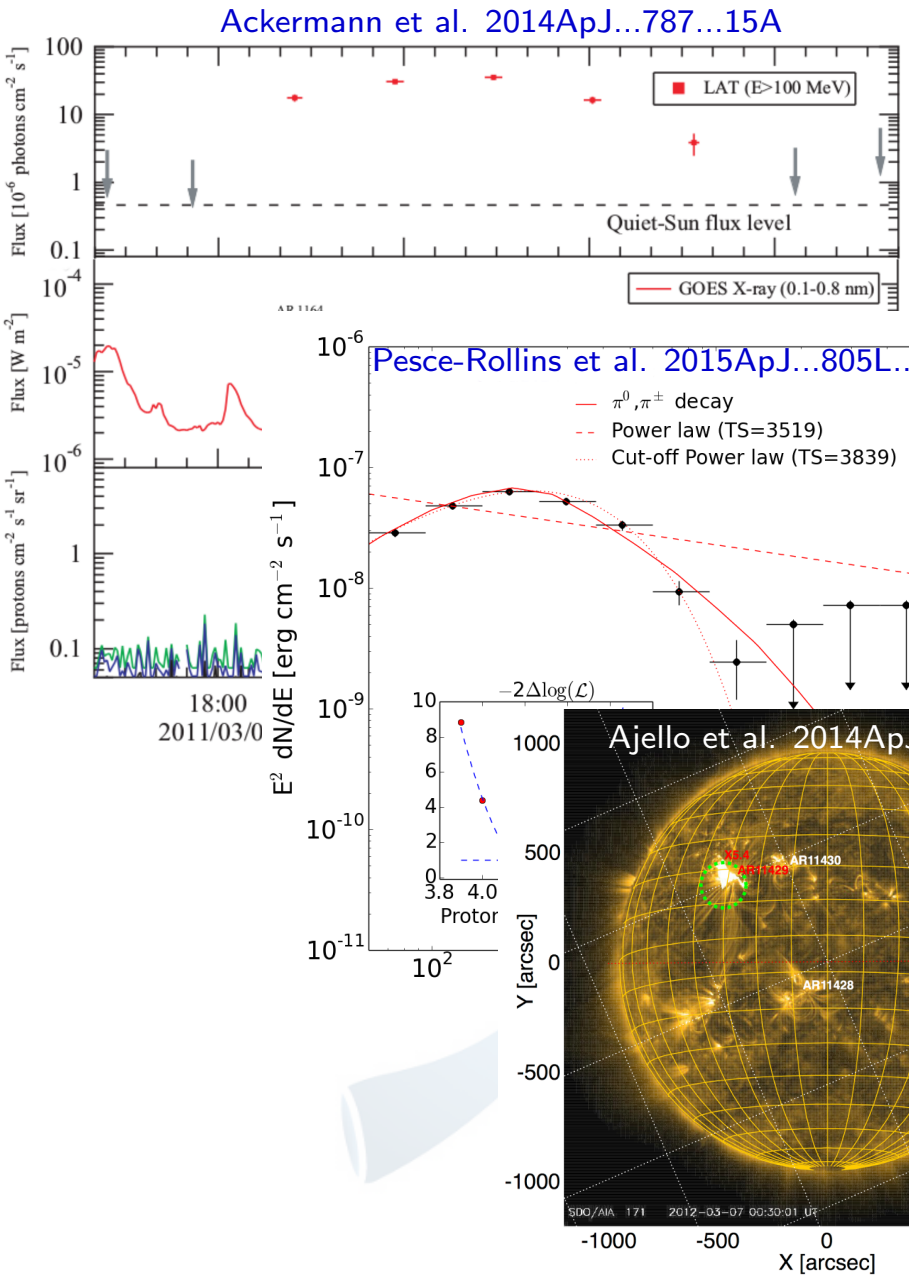
- >100 MeV lasting ~hours from moderate GOES class flares is fairly common
- 13 hours of emission from the M3.7 GOES flare of 2011 March 7

What have we learned so far?



- >100 MeV lasting ∼hours from moderate GOES class flares is fairly common
- 13 hours of emission from the M3.7 GOES flare of 2011 March 7
  - Emission is well described by curved spectrum
  - Pion-decay is the most likely origin

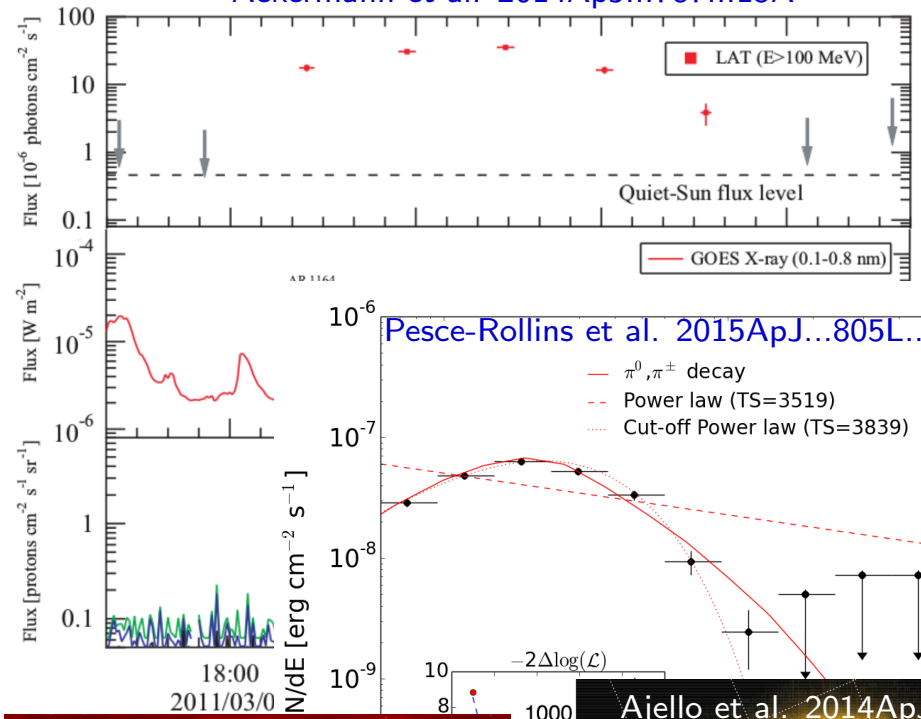
What have we learned so far?



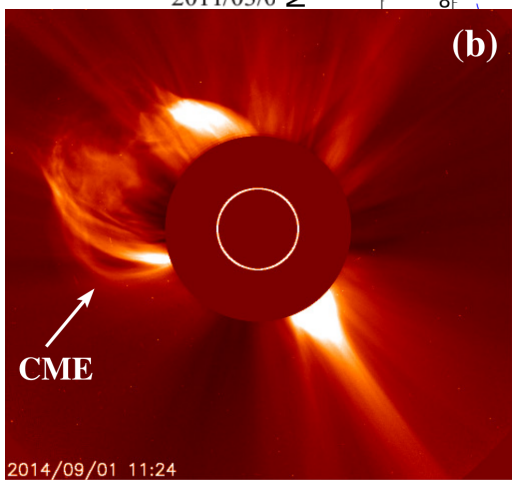
- >100 MeV lasting ∼hours from moderate GOES class flares is fairly common
- 13 hours of emission from the M3.7 GOES flare of 2011 March 7
  - Emission is well described by curved spectrum
  - Pion-decay is the most likely origin
- >100 MeV emission centroid consistent with active region for most bright flares

What have we learned so far?

Ackermann et al. 2014ApJ...787...15A

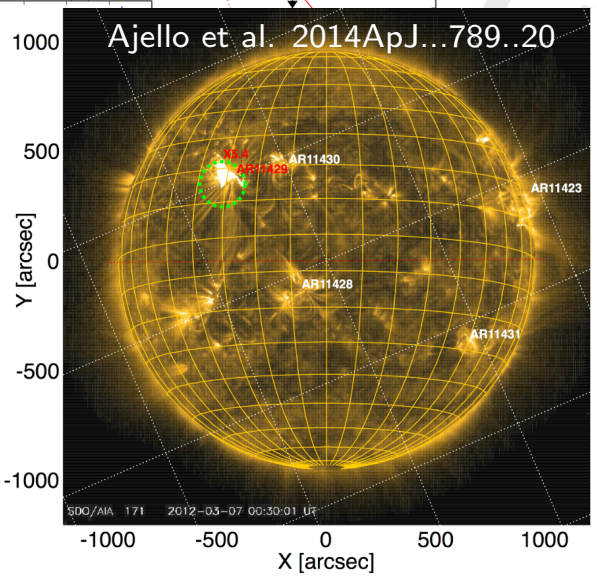


Pesce-Rollins et al. 2015ApJ...805L..15P



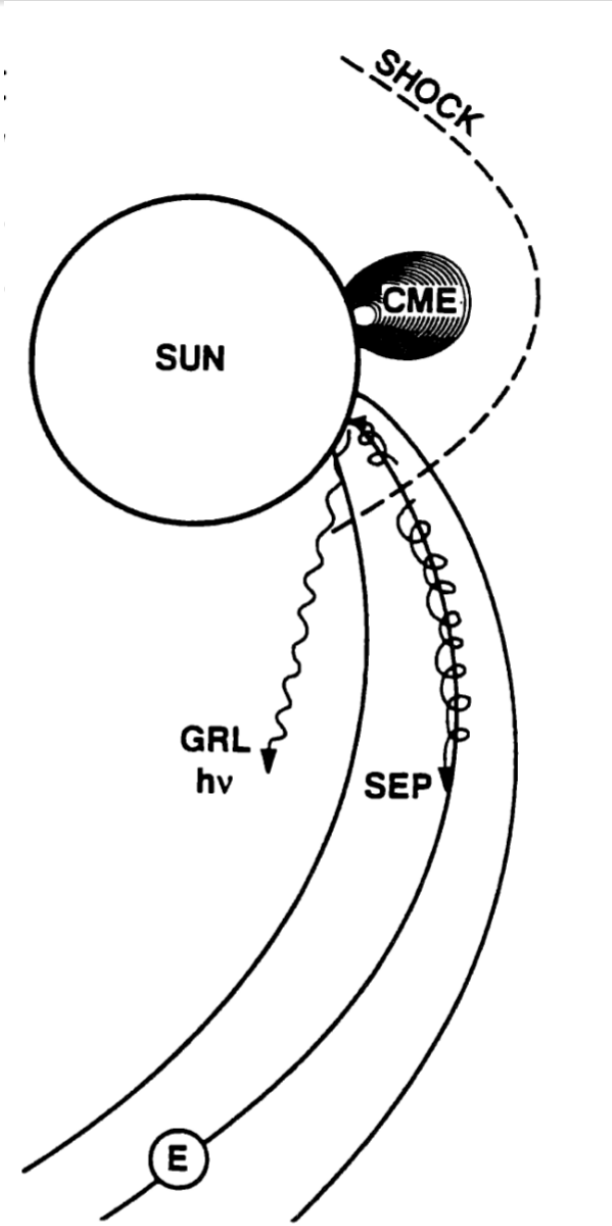
Paper in preparation

Ajello et al. 2014ApJ...789..20



- >100 MeV lasting ∼hours from moderate GOES class flares is fairly common
- 13 hours of emission from the M3.7 GOES flare of 2011 March 7
  - Emission is well described by curved spectrum
  - Pion-decay is the most likely origin
- >100 MeV emission centroid consistent with active region for most bright flares
- All LAT flares associated with fast CME's

Why are behind-the-limb flares interesting?

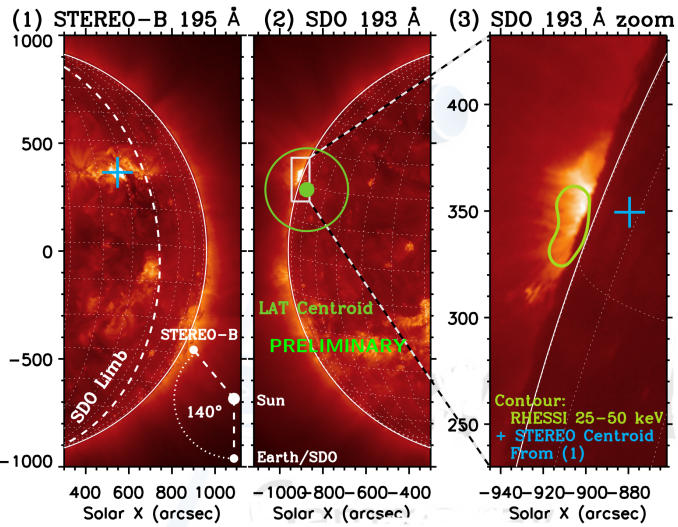


Cliver et al. 1993

- γ-ray emission processes require densities greater than 10^{12} cm^{-3}
- Measurements of γ-ray line emission are generally consistent with a compact region located in the chromosphere
- Observations of γ-rays (both line emission and pion produced) from behind-the-limb flares can imply
  - A spatially extended flare component that can subtend a large range of heliolongitudes
    - Allowing the particles to interact at the visible disk
  - Or acceleration and emission occur in the Corona
    - Requires larger than usual Coronal densities

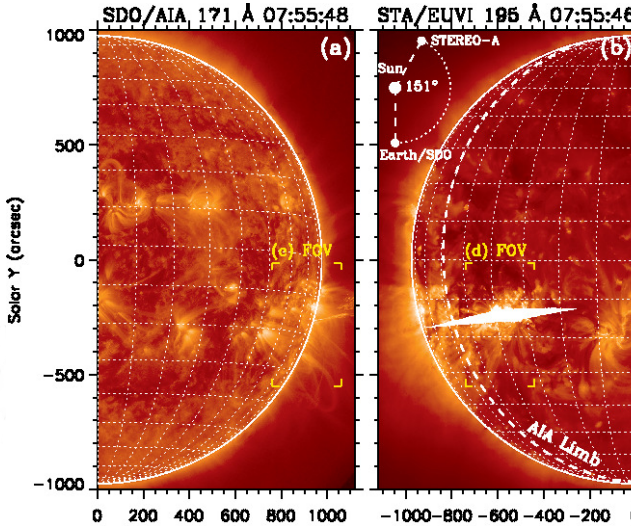
LAT behind-the-limb flares

SOL2013-10-11



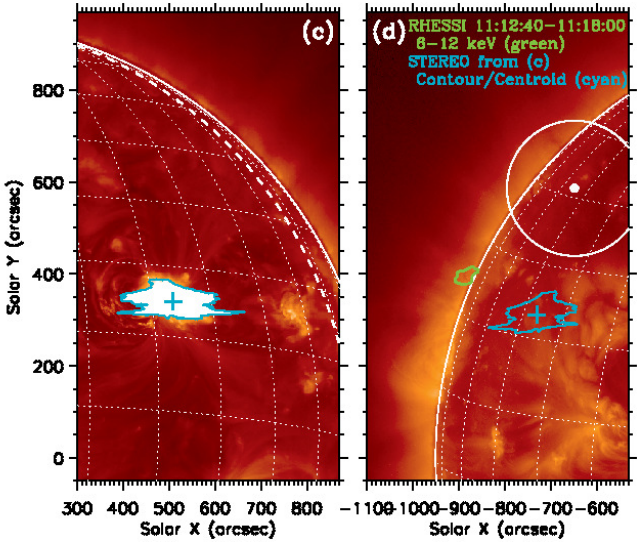
- Located ∼10° behind the eastern limb
- >100 MeV emission for 30 minutes
- *RHESSI* emission consistent with loop top
- Upper limits on nuclear line emission from GBM
- LAT emission centroid consistent with on-disk

SOL2014-01-06



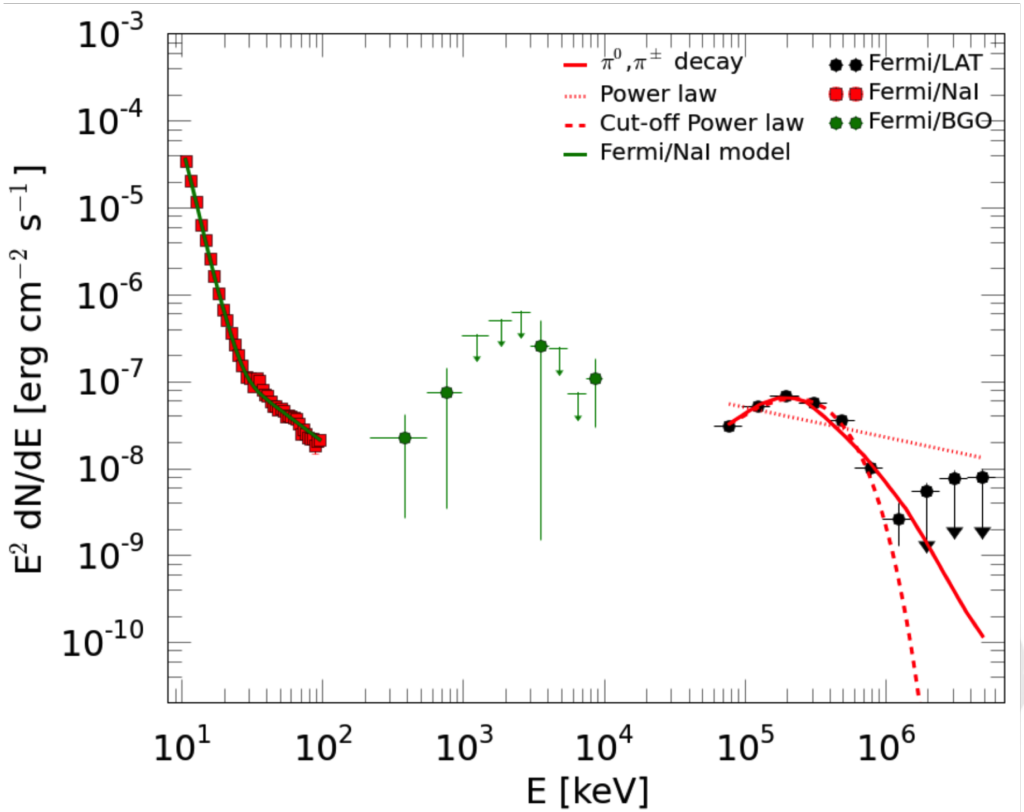
- Located ∼10° behind the western limb
- >100 MeV emission for 20 minutes
- Associated with very strong SEP event
- Gamma-ray onset time consistent with Solar Particle Release time
- Insuffiencent statistics for localization

SOL2014-09-01



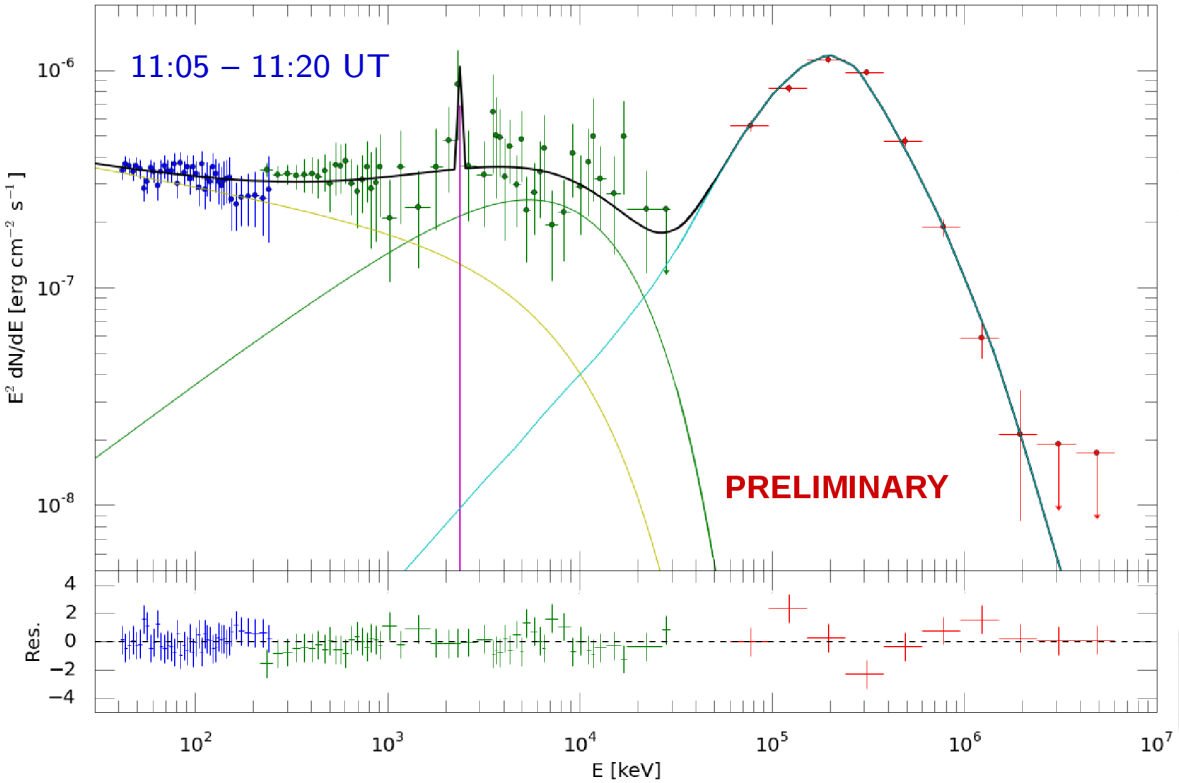
- Located ∼40° behind the eastern limb
- >100 MeV emission for ∼ 2 hours
- *GBM* and *Konus* emission up to few MeV
- 2.23 MeV line visible in GBM
- LAT emission centroid consistent with on-disk

Spectral energy distribution of SOL2013-10-11



- LAT spectra is curved – increase in significance of $\sim 18\sigma$
  - Best proton spectral index is 4.3±0.1
- Only upper limits on the nuclear lines and neutron capture from GBM
- Broken power-law fit to <100 keV GBM emission
  - Photon index 3.22±0.005
  - E_{break} = 20±8 keV

SOL2014-09-01 Spectral energy distribution



1. Pion decay template
2. 2.23 MeV line (gaussian)
3. Power-law exponential cut-off
4. Power-law exponential cut-off

- LAT data is well described by a curved spectrum
  - Best proton spectral index from fit 4.4±0.1
- Power-law (3) index 1.4±0.1, power-law (4) index 2.7±0.1
- Folding energy 8.2±0.2 MeV
- Significance of 2.23 MeV line is $\sim 4\sigma$

Summary

- The *Fermi*-LAT has detected high energy gamma-rays from more than 40 solar flares over the first 7 years of mission
  - Almost half of which are GOES M class
  - Sampling both impulsive and sustained emission
  - Extended emission lasting hours is fairly common
  - $>$100 MeV emission is most likely due to pion-decay
- First detection of $>$100 MeV emission from behind-the-limb Solar flares
  - Flares originate from behind both eastern and western limbs
  - Photons with energies up to 3 GeV measured from two of these flares
  - And 2.2 MeV neutron capture line from SOL2014-09-01
- Behind-the-limb flare observations seem to suggest a spatially extended component for high-energy gamma-rays
  - This component must subtend more 30° heliolongitude
  - Coronal Mass Ejection (CME) generated shocks could accelerate the particles over such a large range
  - Paper on LAT behind-the-limb flares in preparation

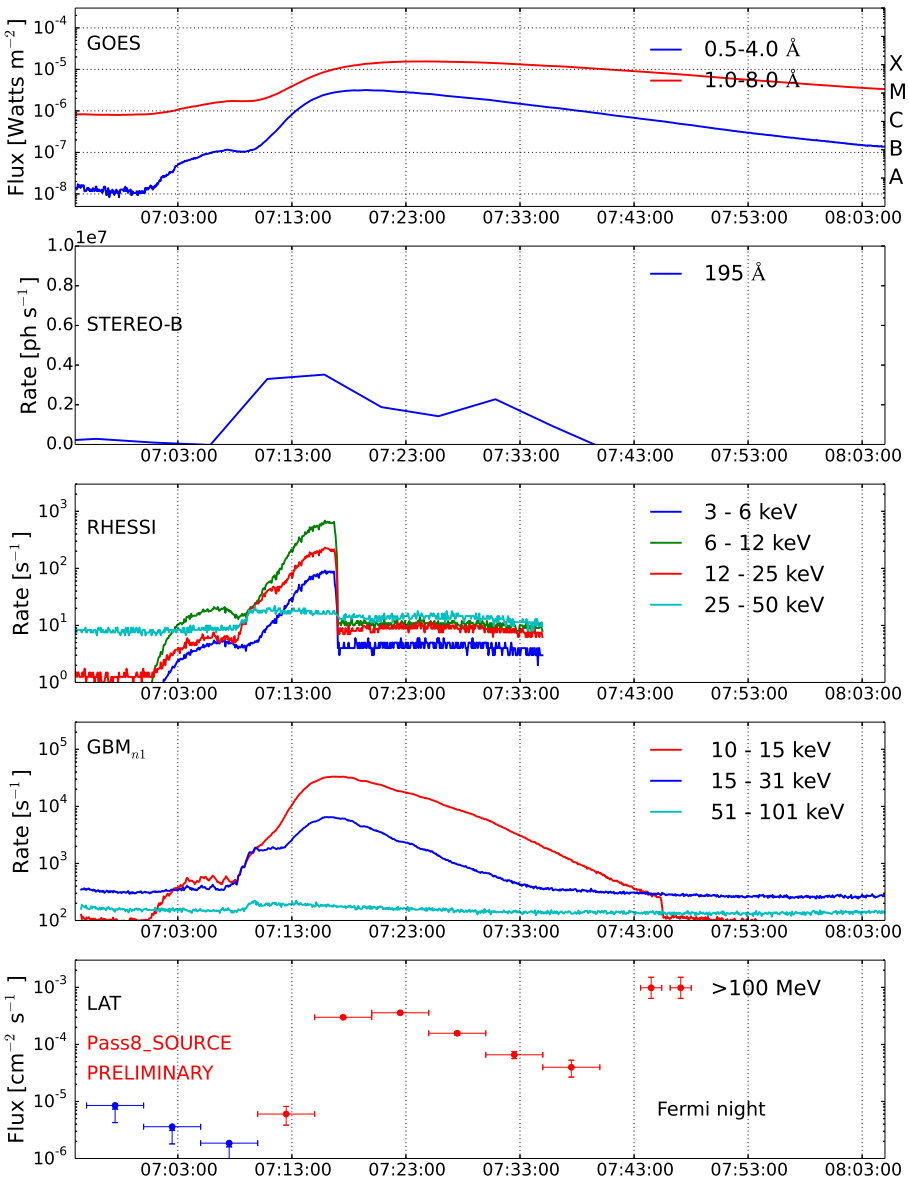
Spare slides

The first gamma-ray behind-the-limb flares

A total of 3 behind-the-limb flares were detected with emission below 100 MeV by space based observatories

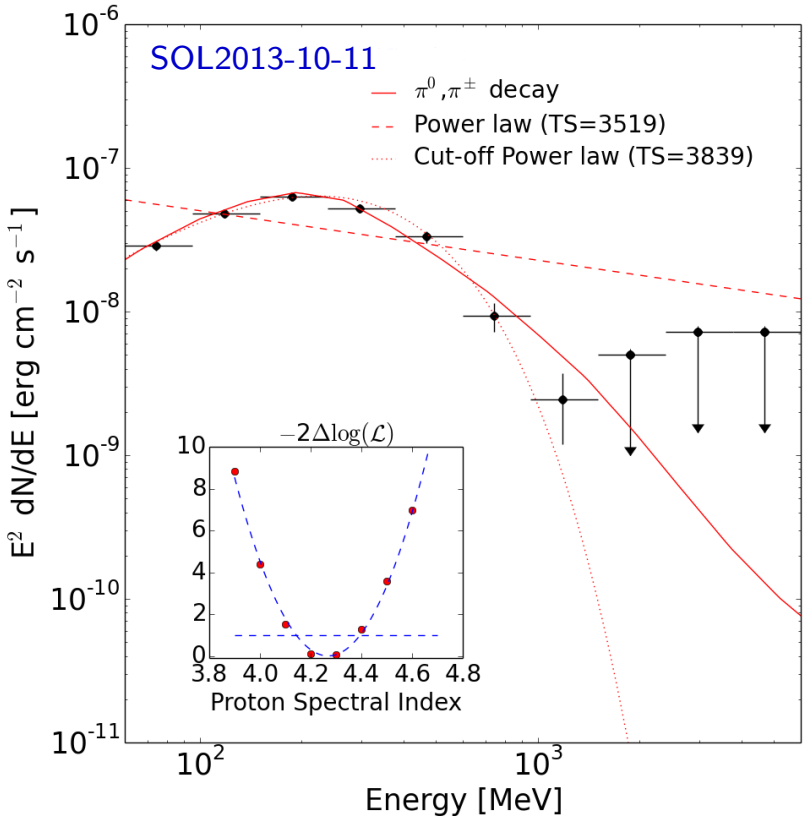
1. 1989 September 29 flare detected by GRS on SMM
   - Vestrand & Forrest 1993, Cliver et al., 1993
   - Intense gamma-ray line emission in the 1-8 MeV range
   - Strong 2.2 MeV neutron capture line
   - Observations required spatially extended flare loop
2. 1991 June 1 flare detected by PHEBUS on GRANAT
   - Barat et al. 1994, Ramaty et al. 1997
   - Intense gamma-ray line emission in the 1-8 MeV range
   - No 2.2 MeV neutron capture line detected
   - Coronal origin for the emission was concluded
3. 1991 June 30 flare detected by PHEBUS, BATSE and EGRET
   - Vilmer et al. 1999, Trottet et al. 2003
   - No detectable line emission or 2.2 MeV line
   - Emission detected up to almost 100 MeV
   - Debate on Coronal or/and extended flare loop emission

First >100 MeV behind the limb flare



- Estimated GOES class from STEREO EUV emission is M4.9
- *RHESSI* and GBM detected emission up to 50 keV above the chromospheric limb
- >100 MeV emission detected for 25 minutes by LAT
- Pass7_REP data published in ApJL, 805, L15
- Re-analyzed the flare with new *Fermi*-LAT Pass 8 data
  - Gained 5 minutes of detection with respect to Pass7_REP
  - Detection from 07:10 - 07:40 UT

Testing the emission models



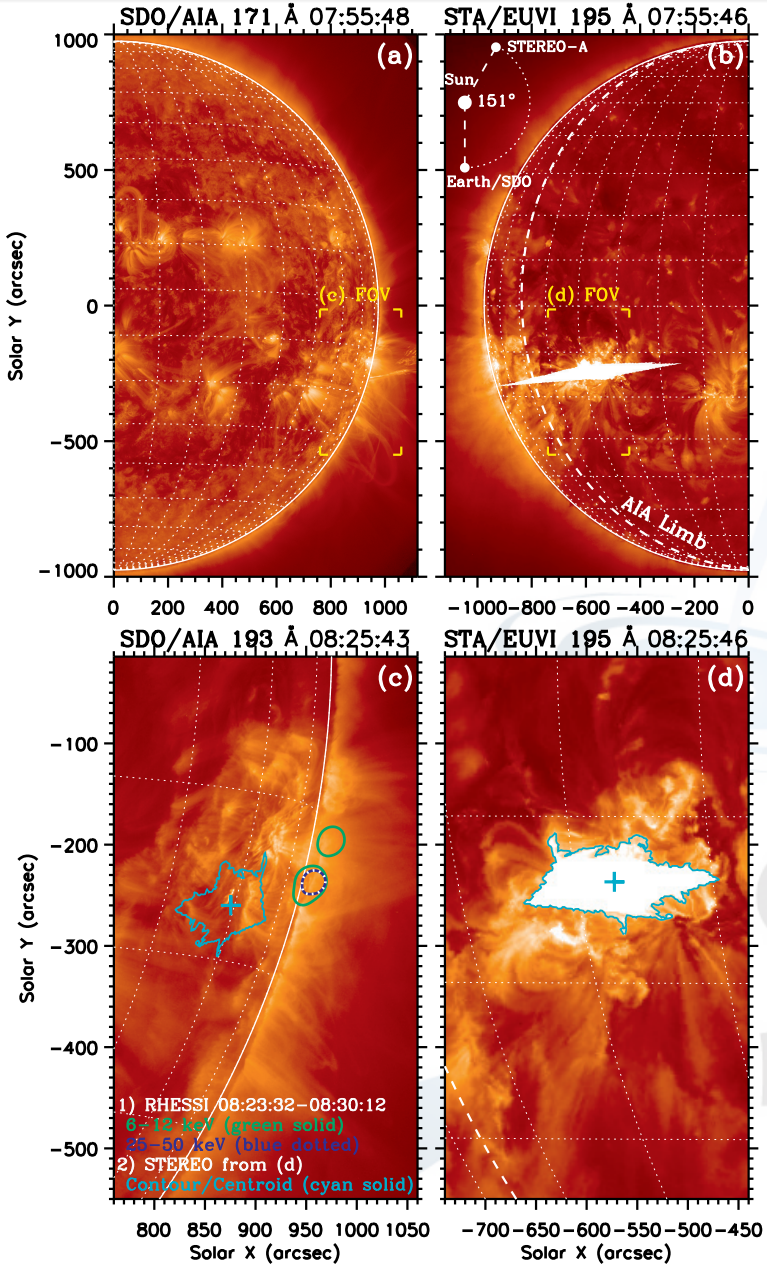
We fit the LAT spectral data between 60 MeV and 10 GeV to test three different emission models:

1. Pure power-law
2. Power-law with exponential cut-off
3. Templates to describe emission from pion decay based on Murphy et al. 1987

We rely on the likelihood ratio test (TS) to estimate the significance of the source and whether the curved model provides a better fit

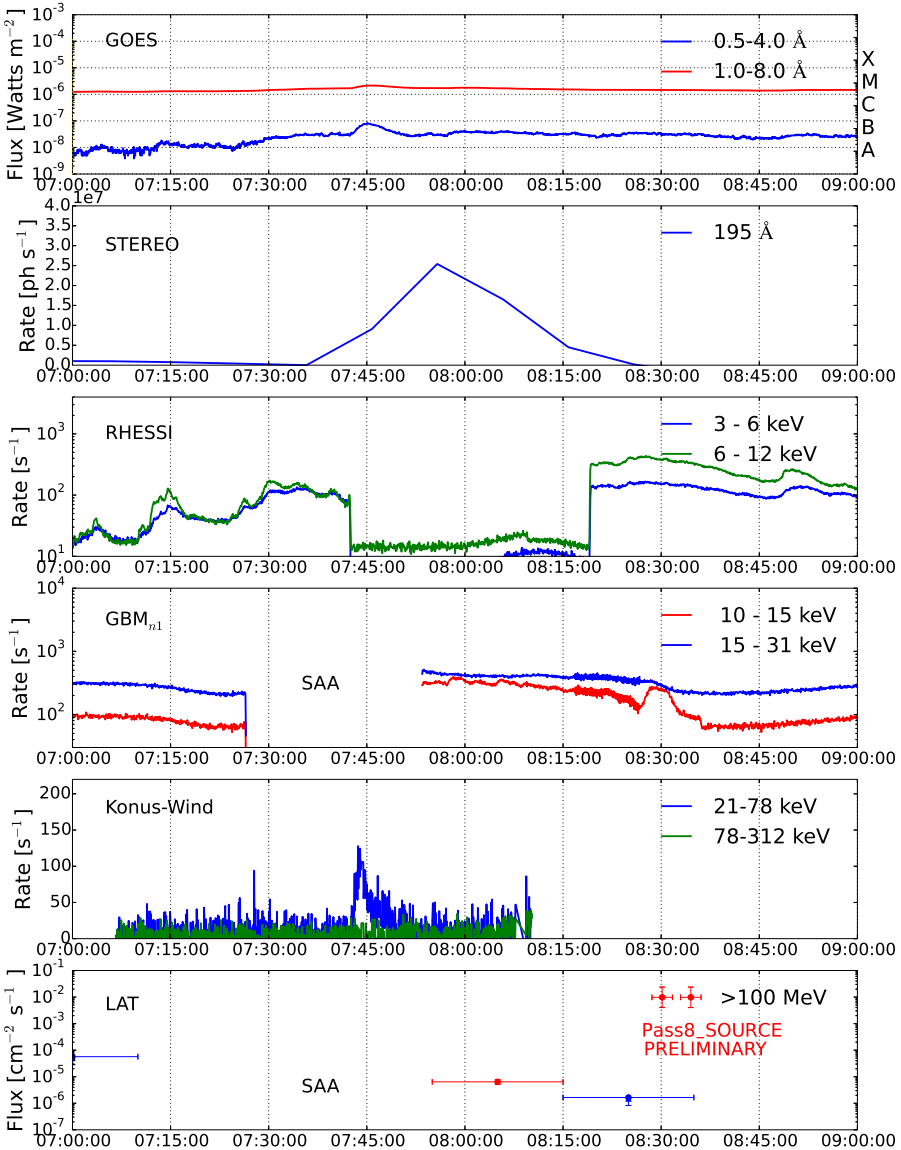
- When model (2) provides a better fit we also fit the data with a series of pion-decay models to determine the best proton spectral index

SOL2014-01-06



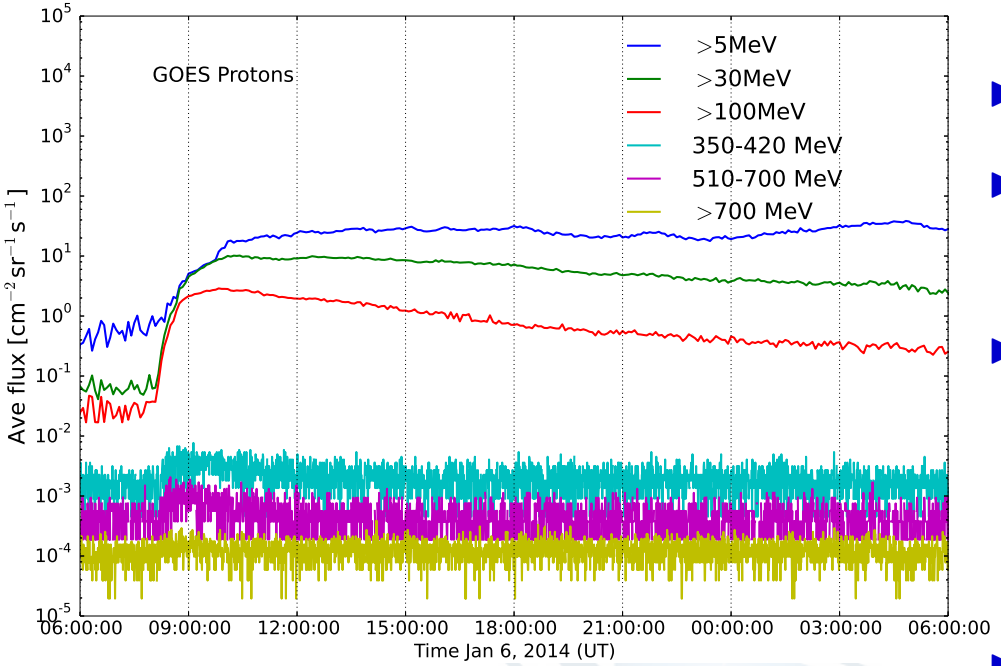
- On Jan 6, 2014 07:42 a flare erupted from an active region located S8W110
  - 20° behind the western limb
- A fast CME (speed ∼1400 km/s) was reported by LASCO
- Filament eruption detected from the visible limb by SDO
- *RHESSI* 6-12 keV source located above the limb
- LAT statistics insufficient to provide localization information

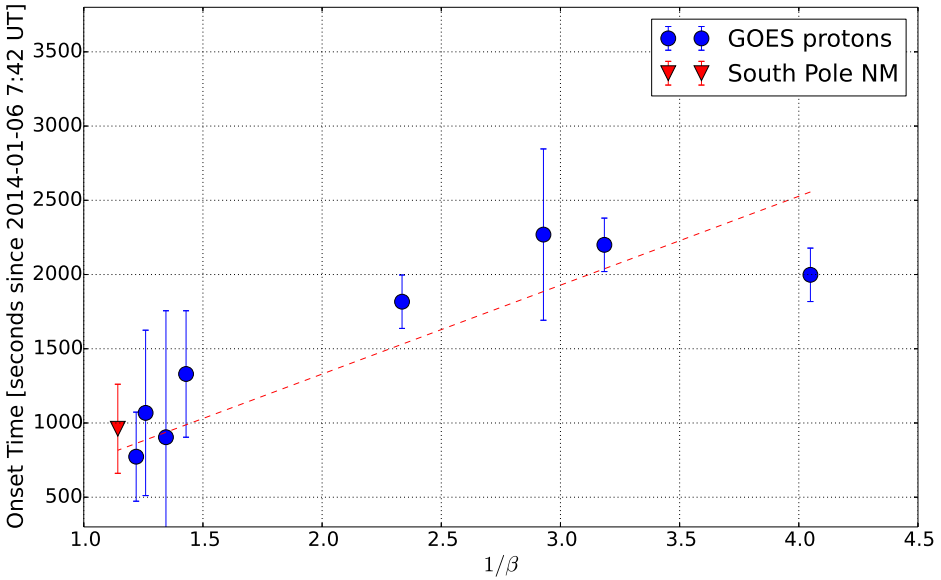
SOL2014-01-06



- Estimated GOES class based on STEREO EUV emission is X3.5
- Konus detected emission up to 78 keV
- *RHESSI* detected emission after 8:20 UT
- *Fermi* satellite was in the SAA from 7:25 - 7:55 UT
- Both detectors on-board *Fermi* detected emission from this flare upon exiting the SAA:
  - GBM detected emission in the 10's of keV range
  - LAT detected >100 MeV emission for ∼20 minutes

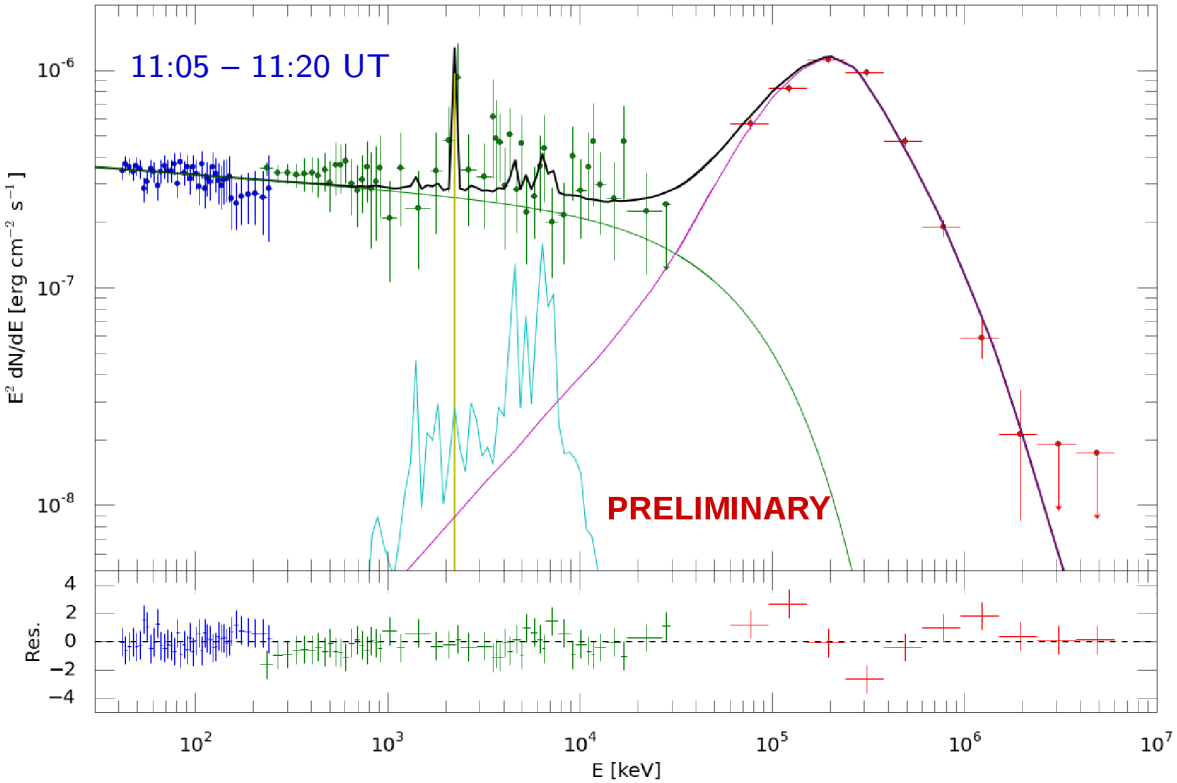
SOL2014-01-06





- Very strong SEP event
- Use SEP onset times to estimate the acceleration time at the Sun
- Fit with a straight line assuming 1.2 AU propagation length gives 07:44 UT on Jan 6, 2014 ($\pm$ 3 minutes)
- In agreement with the Solar particle release time 07:47 UT reported by Thakur et al. ApJL 790, L13
- LAT detection starts 8 minutes later
  - *Fermi* in SAA until 7:55 UT
  - SEP and γ-producing ions accelerated at the same time?

SOL2014-09-01 Spectral energy distribution

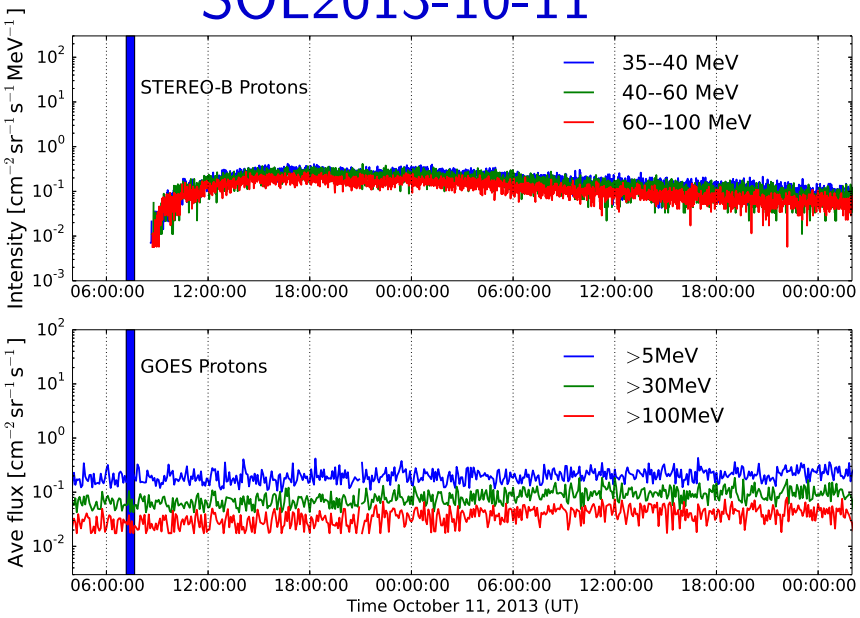


1. Pion decay template
2. 2.2 MeV line (gaussian)
3. Narrow lines template
4. Power-law with EXP cut-off

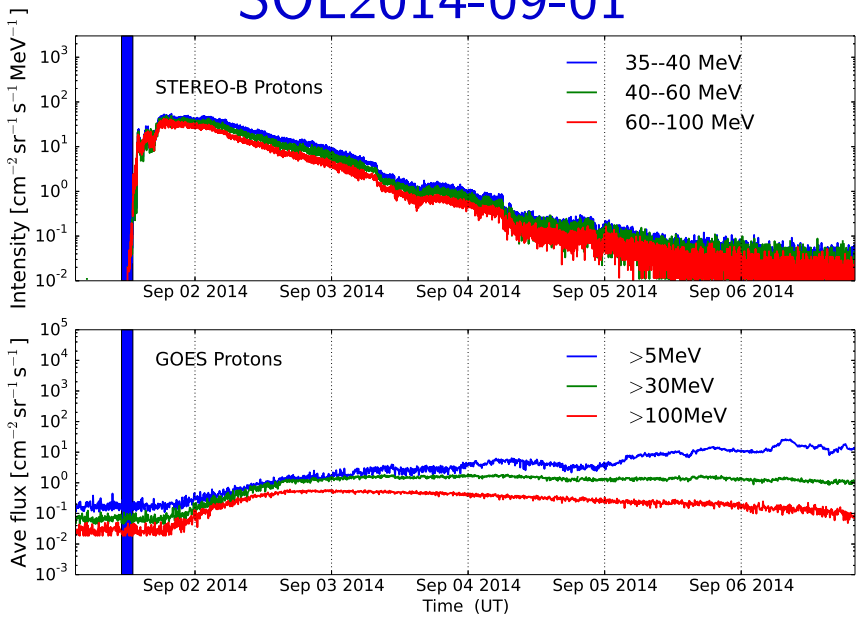
- LAT data is well described by a curved spectrum
  - Best proton spectral index from fit 4.4±0.1
- Photon spectral index 2.1±0.1
- Folding energy 6.7±0.4 MeV
- Significance of 2.23 MeV line and narrow lines is $\sim 7\sigma$

STEREO and GOES protons

SOL2013-10-11



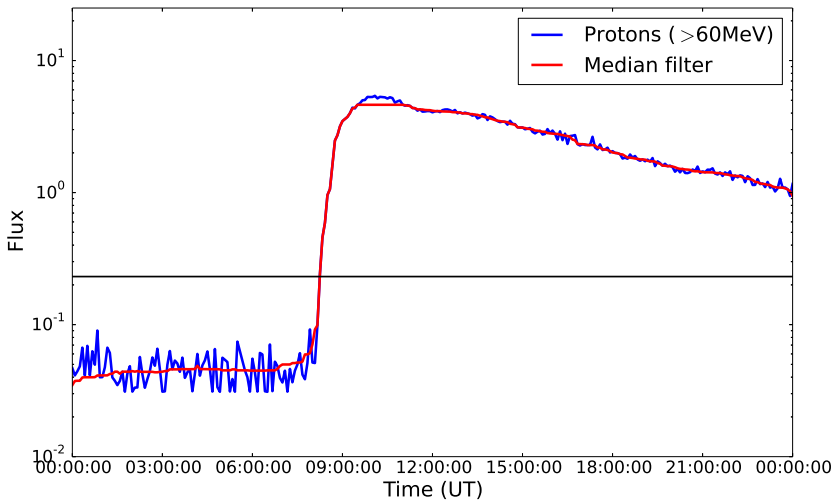
SOL2014-09-01

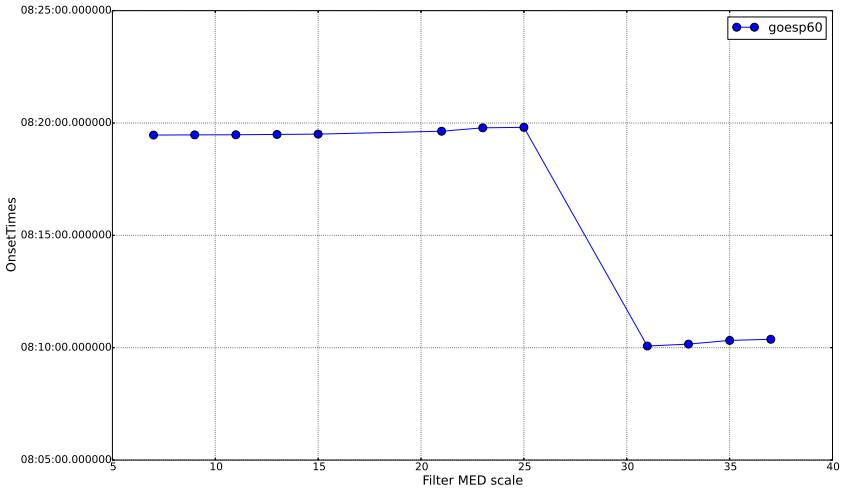


Proton intensity-time profiles provide information on magnetic connectivity and SEP propagation

- SOL2013-10-11
  - Active region located 10° behind eastern limb
  - Poorly connected to Earth – no GOES signal following the flare
- SOL2014-09-01
  - Active region located 36° behind eastern limb
  - Protons reach Earth ∼9 hours after flare

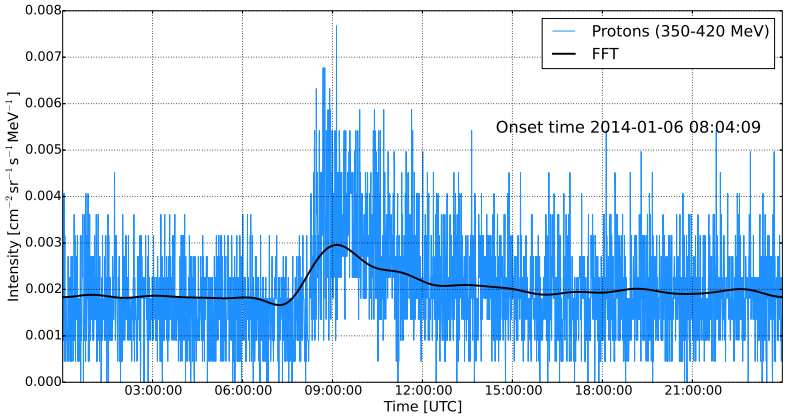
Finding the onset times

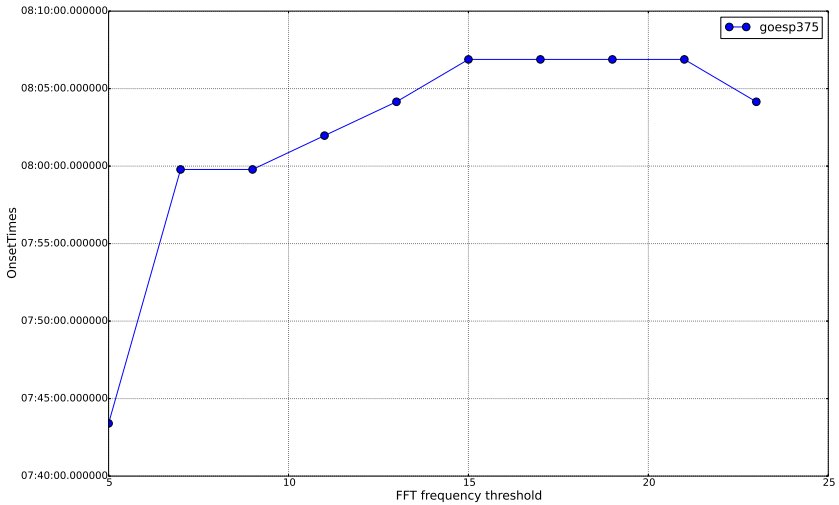




- For GOES SEP we apply a median filtering algorithm to help smooth out the data
- Take the onset time to be the point of 5% max intensity
- We scan over a series of values for the median filter window
- Take median window 25 to be the onset time
- Take the difference in times over the scan values to be the error associated with the onset time

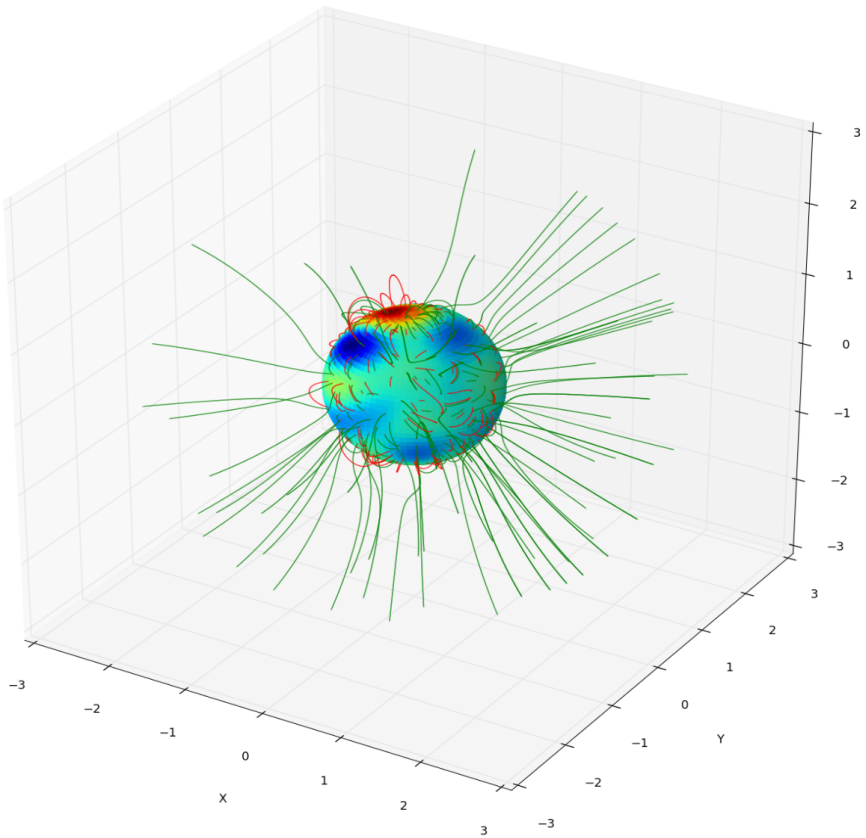
Finding the onset times for HE





- For GOES HE SEP we run an FFT on the data
- Take the onset time to be the point where second derivative is max
- We scan over a series of values for the frequency threshold
- Take frequency threshold of 13 to be the onset time
- Take the difference in times over the scan values to be the error associated with the onset time

Simulations



Toy model simulations

- Spherical harmonics expansion of the magnetic field ($R<R_\odot$)
  - First proposed by Newkirk et al. 1968
- Parker field for $R>R_\odot$
  - Parker 1958, Giacalone & Jokipi 2004
- Particle propagation
  - Ray tracing of particles in magentic field
  - Developing code to take into account the effects of scattering and turbulence

Fermi LLE public data

- LLE catalog of Solar flares and GRBs
- 11 impulsive solar flares and 56 GRBs
- `http://heasarc.gsfc.nasa.gov/W3Browse/fermi/fermille.html`
- All LLE data products publicly available
  - LLE event file
  - spectrum files (PHAII,PHAI and RSP)
  - Quick look files
- LLE data can be analyzed with `XSPEC` and rmfit

Fermi LAT SunMonitor

- Fermi-LAT SunMonitor continuously monitors the Sun
- >100 MeV gamma-ray flux from the Sun in fixed 3 hour time intervals
- All available online!

March 7, 2011 M3.7 class flare
