

Behavioral Simulation using Vivado or VCS

Christos Bakalis / TID / TID-ID-ECS

10 August 2023

Introduction

Most projects follow the architecture depicted on the example on the links below.

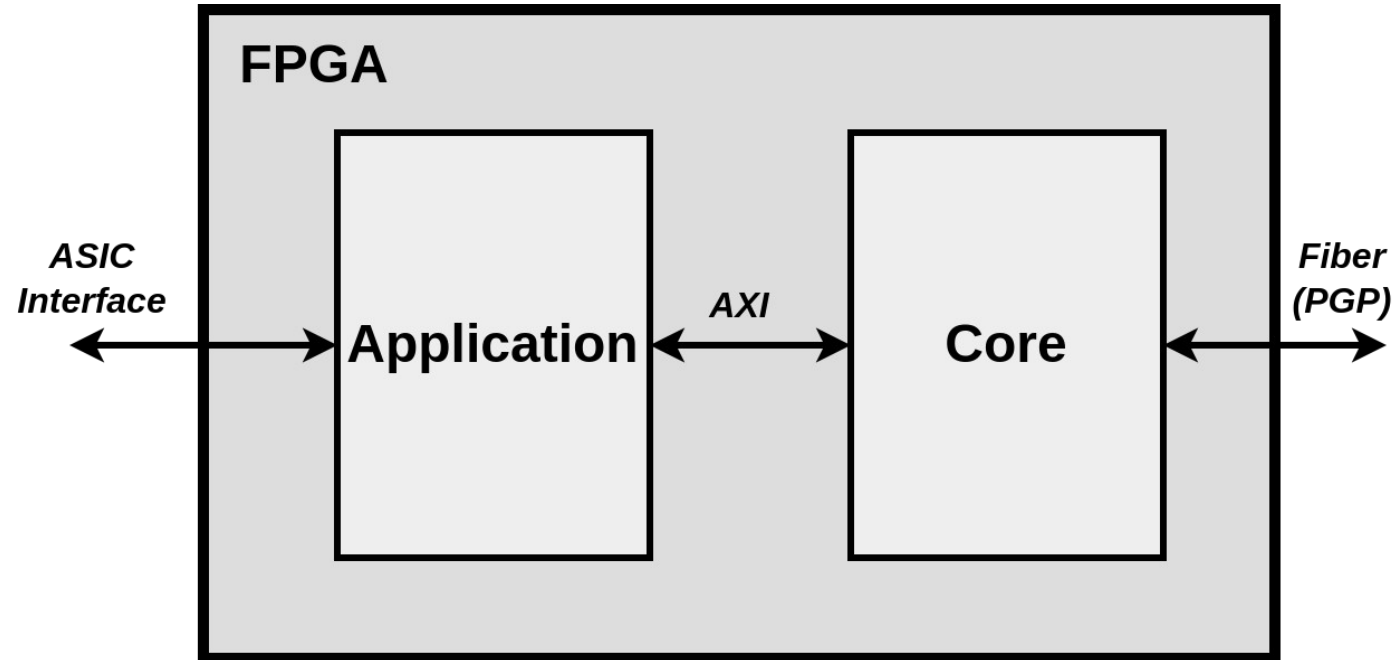

The aim is to create an RTL-based testbench that emulates the implemented design as closely as possible.

If the accompanying software (i.e. rogue) is also included in the simulation process, that is a big plus.

General Architecture for Detector Projects

Recurring theme in all repositories: one Application module (usually what we work with), and one Core module (static – part of the RTL infrastructure of the project)

If not working on a detector-related project, what changes is the fact that the Application module does not implement an ASIC Interface

General Architecture for Detector Projects – Vivado Tb

Sometimes some basic RTL-based model exists, sometimes not

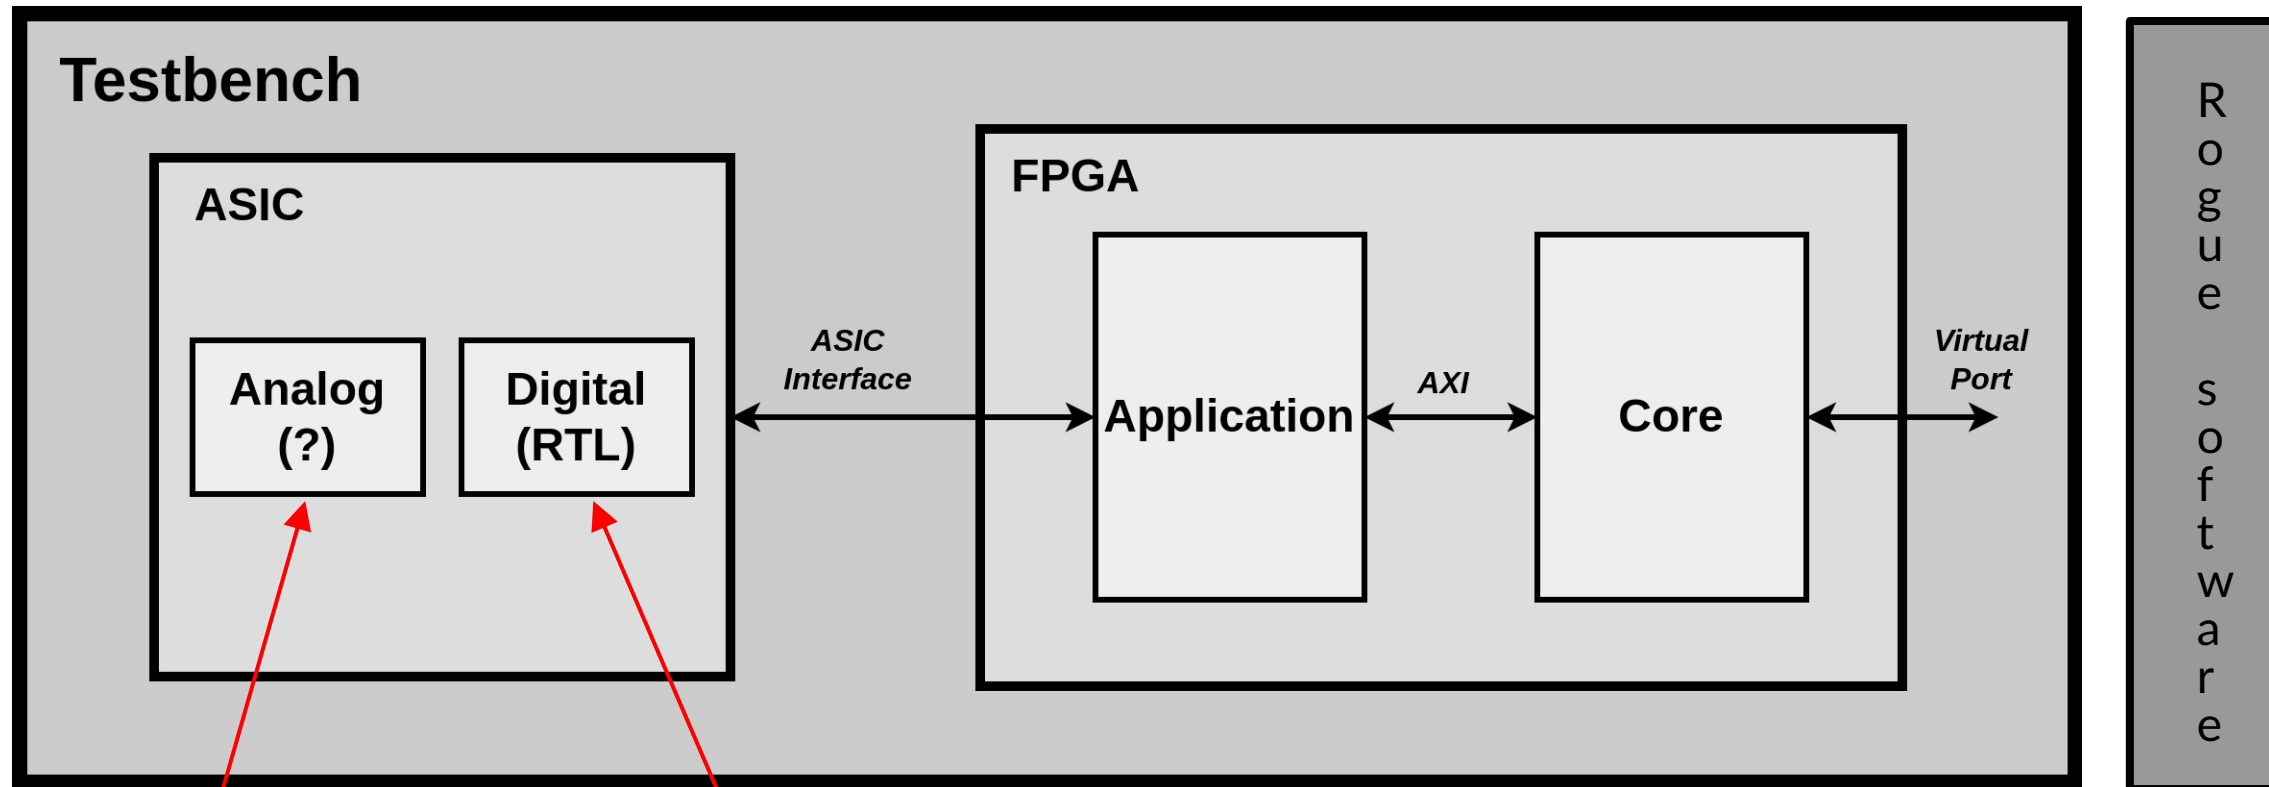

Almost always taken from an ASIC-team managed repo

Fast and easy to put together

Does not include the software

General Architecture for Detector Projects – VCS Tb

Sometimes some basic RTL-based model exists, sometimes not

Almost always taken from an ASIC-team managed repo

Full testbench – emulates the rogue interface via a virtual port

Takes more time to put together – software must be fully working

A fully-simulated project: SparkPix-T | Short Intro

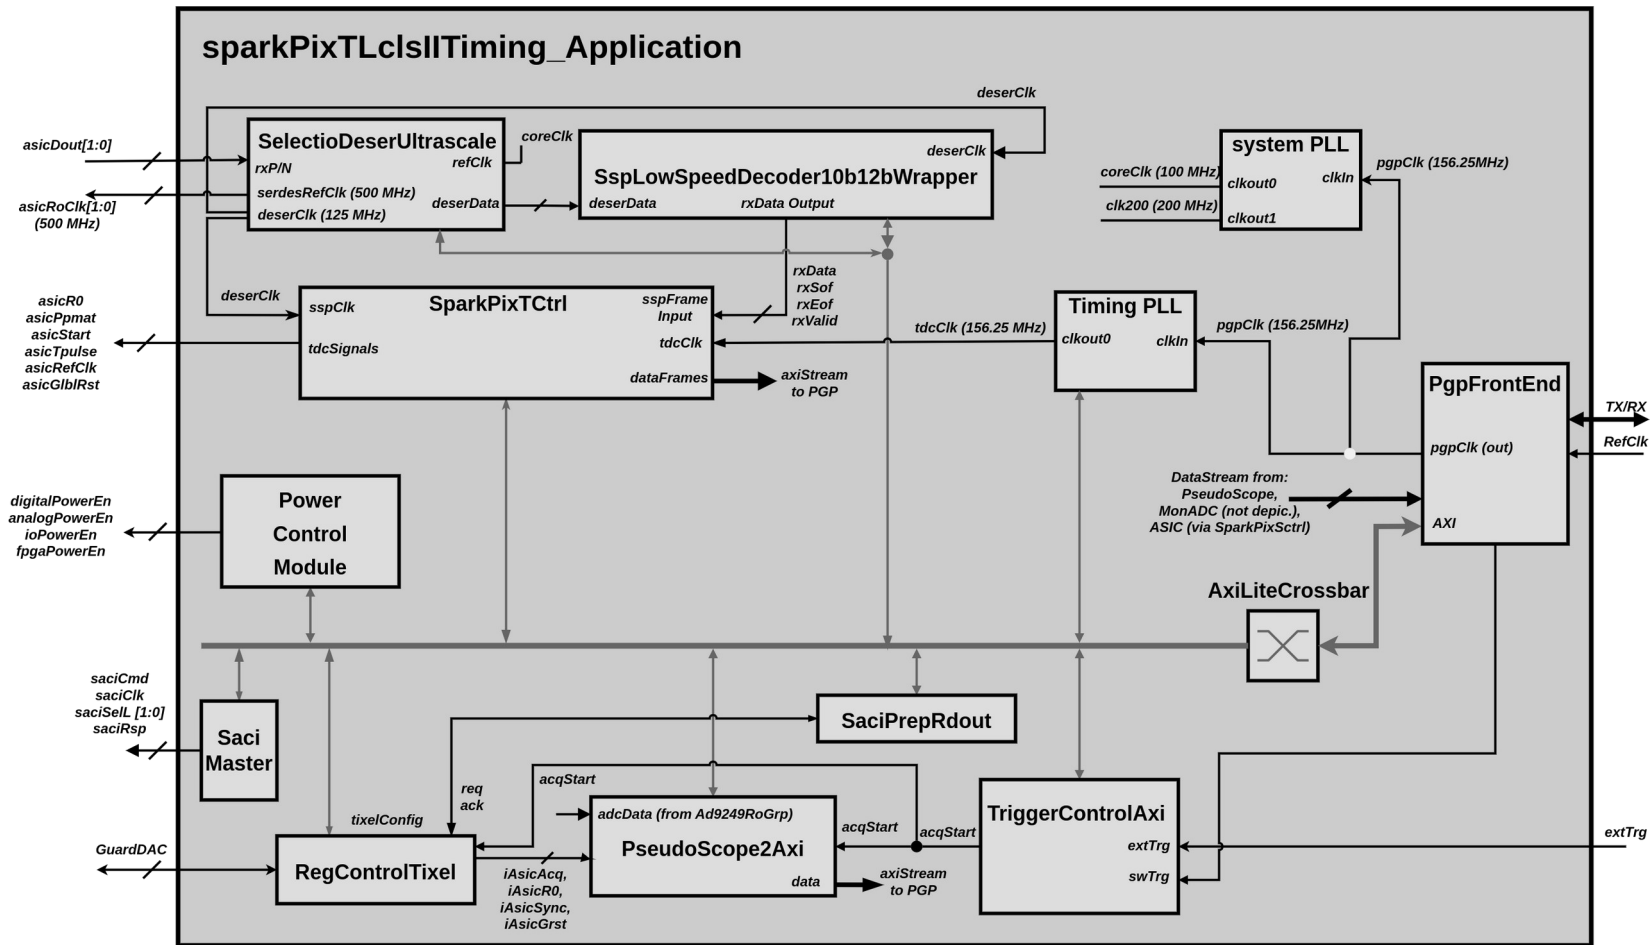

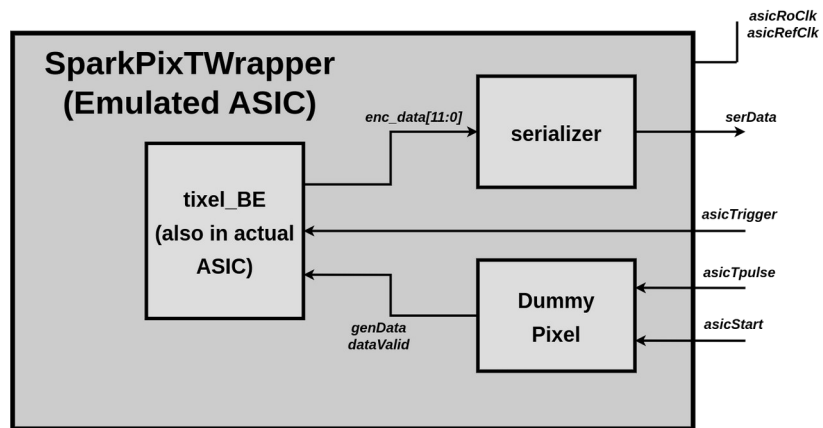

the Data we are Looking for...

...and how we are injecting signals to the ASIC to get that Data

A fully-simulated project: SparkPix-T | Full Block Diagram
