

Source Analysis with *Fermi* LAT Data

Aous Abdo <<u>Aous.Abdo@nrl.navy.mil</u>> National Academy of Sciences & Naval Research Laboratory Washington DC

Overview

- Detection, flux determination and spectral modeling of Fermi LAT sources is accomplished by a maximum likelihood optimization technique.
- * The likelihood analysis is available in two modes, binnded and unbinned. I will be describing the unbinned analysis in this tutorial.
- Full documentations available at:

< http://fermi.gsfc.nasa.gov/ssc/data/analysis/scitools/likelihood_tutorial.html >

Unbinned Likelihood

- * Assuming that one has:
 - Event data file
 - Spacecraft data file
- Steps of the unbinned likelihood analysis:
 - 1. Make the appropriate subselections on the event data file
 - 2. Make counts maps of the region of interest
 - 3. Make an exposure map
 - 4. Obtain the latest isotropic and diffuse models.
 - 5. Create a source model
 - 6. Run the likelihood analysis
 - 7. Make test-statistic maps

Prepare The Data

1. Data selection:

- To perform the likelihood analysis a large ROI (10 20) degrees should be selected. This is especially important for sources in the Galactic plane.
- We will use gtselect to select events in a 10 degree ROI around the CTA1 pulsar:

\$gtselect infile=@events.txt outfile=FT1.fits ra=1.7565 dec=73.02552 rad=10.0 tmin= 292937396 tmax=293543047 emin=100 emax=300000 evclsmin=3 evclsmax=3 zmax=105

- list of event files is contained in the text file events.txt
- We will perform the likelihood analysis on one week of data.
- Select diffuse Class events

Prepare The Data

2. Run gtmktime:

\$ gtmktime

Spacecraft data file[]L100422151847E0D2F37E30_SC00.fits
Filter expression[] DATA_QUAL==1 && LAT_CONFIG==1 && ABS
(ROCK_ANGLE)<52 && IN_SAA!=T
Apply ROI-based zenith angle cut[yes]
Event data file[]FT1.fits
Output event file name[]FT1_gtmktime.fits</pre>

Exclude time periods when some spacecraft event has affected the quality of the data selecting data quality equal 1 (DATA_QUAL==1).

Exclude times when spacecraft was in the SAA

Select LAT configuration intended for science analysis (exclude calibration runs and so on.)

Make Counts Map

\$ gtbin This is gtbin version v2r2p3 Type of output file (CCUBE|CMAP|LC|PHA1|PHA2) []CMAP Event data file name[]FT1_gtmktime.fits Output file name[]FT1_gtmktime_cmap.fits Spacecraft data file name[] Size of the X axis in pixels[]200 Size of the Y axis in pixels[]200 Image scale (in degrees/pixel)[]0.1 Coordinate system (CEL - celestial, GAL -galactic) (CEL|GAL) []CEL First coordinate of image center in degrees (RA or galactic 1)[]1.7565 Second coordinate of image center in degrees (DEC or galactic b)[]73.05225 Rotation angle of image axis, in degrees[]0 Projection method e.g. AIT|ARC|CAR|GLS|MER|NCP|SIN|STG|TAN:[]AIT

Counts Map

Counts Map

 ~100 photons from this relatively bright gamma-ray pulsar survived our cuts over the period of one week!

Make An Exposure Map

1. First we will generate an exposure cube with gtltcube:

\$ gtltcube Event data file[] FT1_gtmktime_292937396-293542196MET.fits Spacecraft data file[] L100422151847E0D2F37E30_SC00.fits Output file[expCube.fits] expCube_292937396-293542196MET.fits Step size in cos(theta) (0.:1.) [0.025] Pixel size (degrees)[1] Working on file L100422151847E0D2F37E30_SC00.fits

2. Then we will use the exposure cube we made to make the exposure map with gtexpmap -->

Make An Exposure Map

- Eerthi
- gtexpmap creates an exposure map based on the event selection used on the input photon file and the livetime cube.
- The exposure map must be recalculated if the ROI, zenith, energy selection or the time interval selection of the events is changed.

SCIENCE DIVISION

Make An Exposure Map

- Note that we selected for the exposure map a source radius that is larger than the acceptance cone radius.
- This is necessary to ensure that photons from sources outside the ROI are accounted for owing to the size of the instrument point-spread function especially at lower energies
- Half-degree pixels are a nominal choice; smaller pixels should result in a more accurate evaluation of the diffuse source fluxes but will also make the exposure map calculation itself lengthier.
- The number of energies specifies the number of logarithmically spaced intervals bounded by the energy range given in the DSS keywords. A general recommendation is 10 bins per decade. This is sufficient to accommodate the change in effective area with energy near 100 MeV.

Exposure Map

 Exposure map of the 15 degree region around CTA1 for the first energy bin (100-152 MeV)

* Scale is in cm² s

- * To account for all sources in the region of interest we need to model the Galactic diffuse and the isotropic emissions.
- Those models are available here: < <u>http://fermi.gsfc.nasa.gov/ssc/data/access/lat/BackgroundModels.html</u> >
- * Use the "gll_iem_v02.fit" file to model the Galactic diffuse and the "isotropic_iem_v02.txt" file to model the isotropic emission.
- Details of these models are available on the same link above.

- In addition to the Galactic diffuse and the isotropic models we need to have in our source model all the Fermi LAT point sources.
- * For this we need to download the latest Fermi LAT catalog from:

<<u>http://fermi.gsfc.nasa.gov/ssc/data/access/lat/1yr_catalog/</u>>

* One then needs to extract the point sources in the source region. For this we will use the contributed python script xmlModelEditor.py with the catalog in its xml format (file "gll_psc_v02.xml)

xmlModelEditor.py

Reads a Fermi xml model file and creates a subset of the given file around a given source with a user-specified ROI. The user can specify an ROI in which some of the spectral parameters of a given source are kept free. The user can also add the standard diffuse models or specify his own.

```
$ xmlModelEditor.py --ra 1.7565 --dec 73.02552 -a 15 -i ./Catalog/
gll_psc_v02.xml
You didn't specify a name for the output file. I will be using "srcmodel.xml"
as the name of the file
There are 25 sources in the xml file
```

* This will create an xml file "srcmodel.xml" that contains all 25 point sources in the 1FGL catalog around the CTA1 pulsar in a 15 degree region.

xmlModelEditor.py

- To add the diffuse models just use the --diff option and point to the diffuse model files with the --gal and the --egal options.
- We will free the integral and spectral index parameters for all sources that are within 5 degrees of our source. We use the --roifree option for this.
- * The selection of 5 degrees in the "free spectral parameter" region is arbitrary but in general one needs not to go below 5 degrees of the source. Freeing all sources in the ROI will make gtlike slow.

\$ xmlModelEditor.py --ra 1.7565 --dec 73.02552 -a 15 --roifree 5 --diff -gal ./BackgroundModels/gll_iem_v02.fit --egal ./BackgroundModels/ isotropic_iem_v02.txt -i ./Catalog/gll_psc_v02.xml You didn't specify a name for the output file. I will be using "srcmodel.xml" as the name of the file There are 25 sources in the xml file
